

Incident review: EU delivery latency

INC-001 / June 14, 2026 / Final review

Severity	SEV2
Region	eu-west
Customer impact	Delayed webhook dispatch
Data loss	None

Executive summary

A worker queue imbalance in eu-west increased webhook queue time for 47 minutes. Payload execution time and customer endpoint response time remained normal. The incident affected multiple organizations assigned to eu-west while US regions stayed within baseline. No customer configuration change was required.

Customer-visible evidence

Affected runs show rising time between `queued_at` and `dispatched_at`, followed by normal execution duration. Support should correlate cases using organization region, the incident window, and queue-time metrics. A nearby incident with a different region or failure mode is not sufficient evidence.

Timeline (UTC)

11:52	Alert fired for eu-west queue age.
12:00	Incident declared; worker imbalance confirmed.
12:11	New work redistributed across healthy workers.
12:31	Queue age returned below two minutes.
12:47	Backlog cleared; incident moved to monitoring.

Support guidance

Preserve affected run IDs, explain that deliveries were delayed rather than lost, and avoid asking customers to rotate secrets or change endpoints. Escalate cases where execution duration, destination errors, or impact time falls outside this incident.

Technical analysis

Queue imbalance and recovery evidence

Root cause

A deployment changed worker lease renewal timing. Under uneven partition ownership, several workers retained fewer partitions while two workers accumulated a backlog. Automatic scaling added capacity but did not immediately rebalance existing leases.

Why retries were not the remedy

Runs had not reached the destination, so creating manual retries would have added work to the same regional queue. Once dispatch occurred, destinations acknowledged normally. The correct mitigation redistributed queued work and preserved original delivery IDs.

Corrective actions

Complete	Lease timing reverted and guarded by configuration validation.
Complete	Queue-age alert split by region and partition.
Planned	Load test adds uneven partition ownership scenario.
Planned	Support incident view exposes queue and execution duration separately.

Evidence citation: this review supports region-specific latency investigations only when case time, home region, affected component, and queue-delay failure mode match.
